### **Highlights**

- LEAP demand projection for Ghana from 2010 to 2014.
- Develop scenarios using an adaptation of Schwartz's scenario approach.
- Develop LEAP model for generation scenario.
- Each scenario represents possible generation expansion strategy.
- High renewable energy systems penetration results in net economic and environmental benefits.

## 1 **1. Introduction**

2 Ghana faces serious energy related challenges as the country struggles to meet generation  
3 requirement. The electricity supply system of the country is characterised by power outages  
4 which has serious implications on the quality of life as well as industrial development. Stable  
5 electrical energy is important with the recent development of the country's oil and gas  
6 industry which has the potential of attracting investors to the expected oil and gas driven  
7 economy in the near future, since reliable and affordable electricity generation system is an  
8 indispensable commodity in the technological development of any country. Even though the  
9 country is unable to meet the current demand, the future demand is projected to be increasing  
10 at 10% per annum (Abledu, 2013). This does make the development of a realistic generation  
11 expansion plan very essential if the country is to achieve its medium to long term  
12 development goals. Inadequate appropriate expansion has resulted in the current situation  
13 where the generation capacities can only meet about 65% of the current demand (March  
14 2014) (Energy Commission, 2015)

15 The conventional grid generation in Ghana is by Hydro, with the Akosombo Hydro  
16 dam providing almost all the grid power when it was commissioned in 1966 (Aryeetey,  
17 2005). The Akosombo generating plant was originally constructed with a total installed  
18 capacity of 588 MW. The capacity was increased to 912 MW in 1972 with an addition of two  
19 generating units to the original four. (Aryeetey, 2005). The construction of the Akosombo  
20 hydro plant was tied to the Volta Aluminium Company (VALCO). The idea was to develop  
21 the huge bauxite reserves in the country to make use of the energy from the Akosombo dam  
22 (VALCO, 2016). The smelter was subsequently constructed consisting of five portlines  
23 capable of producing 200 000 MT of primary aluminium annually. The company today which  
24 is now 100% owned by the Government of Ghana operates about 20% its rated capacity as a  
25 result of insufficient supply of power (Energy Commission, 2015). An additional hydro dam,  
26 the Kpong dam, was constructed near Akuse, 24 km downstream of Akosombo dam. The  
27 Kpong hydroelectric plant was commissioned in 1982 with an installed capacity of 160 MW  
28 (Aryeetey, 2005). Thermal power generation was introduced to supplement the conventional  
29 Hydroelectricity after a drought in 1983 underscored the need to diversify the country's  
30 generation system. The introduction of Thermal power generation into the generation mix of  
31 the country occurred in 1997 with the construction of a combined cycle power plant with an  
32 installed capacity of 330 MW at Aboadze near Sekondi-Takoradi. The Takoradi Thermal  
33 Power Station (TAPCO), as it is officially called, was eventually expanded to 550 MW with

34 the addition of 2x110 MW combustion turbine plants in 2000. This marked the beginning of a  
35 gradual shift to thermal generation in the country. The installed capacity as at March 2014  
36 was 2851MW which is made up of 1580 MW (55.4%) from the three hydro dams, 1248 MW  
37 (43.77%) from Thermal plants and only 2.5 MW (0.09%) from photovoltaic plant (Energy  
38 Commission, 2015). All the plants are operated by Volta River Authority (VRA) except Bui,  
39 which is operated by Bui Power Authority (BPA). VRA and BPA are both government  
40 agencies. Sunon-Asogli, and CENIT are private entities which contribute about 11.61% of  
41 the installed capacity (Energy Commission, 2015).

42 There is a growing interest in power generation systems worldwide because of the  
43 growing demand of power and the environmental implications of these power systems. The  
44 adverse environmental and societal impacts and fluctuation in the prices of fossil fuels in the  
45 world market has necessitated the exploitation of sustainable power generation technologies.  
46 Ghana is endowed with a number of renewable energy resources which can be exploited to  
47 help meet the energy needs of the country. There an excellent solar radiation all year round,  
48 and in every part of the country, with an average radiation of 5.5kWh/m<sup>2</sup>. Sites suitable for  
49 medium and small hydro power plants have also been identified in various part of the country  
50 with a potential of adding over 900 MW to the national grid if fully exploited. Sites near the  
51 coastal parts of the country have also been identified with excellent conditions for wind  
52 thermal generation (Gyamfi, et al., 2015).

53 The scenario approach was adopted to examine the possible pathways that future  
54 generation system in Ghana could evolve. Scenario approach is a key techniques applied by  
55 futurists in various disciplines to develop strategic plans and policies. Several definitions of  
56 scenario exist in literature, however the definition of the Intergovernmental Panel on Climate  
57 Change (IPCC) summarises the concept of scenario analysis as applied to the natural sciences  
58 (IPCC, 2013): "*A scenario is a coherent, internally consistent and plausible description of a  
59 possible future state of the world. It is not a forecast; rather, each scenario is one alternative  
60 image of how the future can unfold*". It is deduced from this definition that scenarios are not  
61 predictions, and hence do not forecast, but rather present alternatives of possible outcomes.  
62 The term scenario as it is applied in strategic planning was pioneered by Herman Khan and  
63 was originally applied in military studies in the 1950s (William, 1988). The concept has since  
64 been applied in an increasing number of disciplines: Kahn and Wiener developed scenarios to  
65 explore the consequences of nuclear proliferation at the heart of the cold war (Kahn &  
66 Wiener, 1967) , while Brewer applied the concept to explore policies for Europe forestry

67 sector (Brewer, 1986). The Intergovernmental Panel on Climate Change (IPCC) has applied  
68 this methodology by developing emission scenarios in its assessment reports (IPCC, 2016) .  
69 The application of scenarios for the energy studies are inspired by the work of Lovins who  
70 developed scenarios for Soft Energy Paths (SEP) (Swart, et al., 2004). Most recent energy  
71 scenarios with continental focus include Energy Technology Perspectives (IEA, 2014),  
72 International Energy Outlook (EIA, 2014), Greenpeace’s Energy Revolution (Teske, et al.,  
73 2015) and World Energy Outlook (OECD/IEA, 2013) . At the national level, scenarios were  
74 employed for assessing alternative energy pathways in California (Ghanadan & Koomey,  
75 2005), Venezuela (Bautista, 2012), Korea (Park, et al., 2013), Panama (McPherson &  
76 Karney, 2014) and most recently, for environmental assessment of energy production from  
77 landfill gas plants in Tehran (Nojedehi, et al., 2016).

78 In Ghana, scenarios approach was applied to develop the strategic national energy  
79 plan from 2006 to 2020 (Energy Commission, 2006). This study examines three pathways:  
80 option1 is an expansion plan based on thermal and 10% Non-conventional Renewable Energy  
81 Technologies (NRET)<sup>1</sup> by 2020; option 2 based on thermal, Bui hydro and 10% NRET and  
82 option 3 is thermal, nuclear and 10% NRET. The current study presented in this paper made  
83 use of option 2 which represents the current official expansion plan as the base case scenario  
84 and explores the performance of generation system with higher levels of NRET. The aim of  
85 the analysis is to provide a framework that could lead to discussion for the development of  
86 renewable energy technologies in Ghana. Nonetheless, these scenarios can never be an  
87 exhaustion of all possible pathways. However, the findings in this paper will provide a useful  
88 platform for discussions with stakeholders and energy policy planners.

## 91 **2. Methodology**

### 92 **2.1. Scenario Framework**

93 Due to the diverse nature of the application of this technique, various methodologies have  
94 been developed to guide scenario development. The scenarios in this paper were developed to  
95 explore possible developments in the supply side of the generation system of Ghana using an  
96 adaptation of the Schwartz’s scenario planning methodology (Schwartz, 1991). Schwartz’s  
97 scenario methodology is one of the most comprehensive methods of scenario building and  
98 has been applied widely in literature for scenario planning. An adaptation of Schwartz’s

---

59 <sup>1</sup> NRET does not include large hydro generation

99 approach was used in developing scenarios to explore energy pathways in California  
100 (Ghanadan & Koomey, 2005). A framework developed to support environmental decision  
101 making was also based on this methodology (Mahmoud , et al., 2009). Schwartz’s approach  
102 was also employed for analysing alternative generation pathways for the Panama’s electricity  
103 sector Figure 1 shows the framework used in the development of the scenarios in this paper  
104 (McPherson & Karney, 2014).

Figure 1 Framework for Scenario development  
(Schwartz, 1991)

**Step 1: Identifying focal issue:** the construction of scenarios begins with identification of  
the main topic or idea and building outward. The focal point of this paper was to explore the  
suitability of high integration of Renewable Energy Technologies (RET) in Ghana.

**Step 2: identification of key variables:** the second stage involves listing the key variables  
influencing the outcome of the decision as well as the social, economic, political,  
environmental and technological forces that influence the key factors. Examples of key  
variables that influence the generation sector of Ghana includes energy security and  
reliability, types of RET technologies, RET potential, cost of fuel, technical capacity, Cost of  
technologies as well as economic and population growth rates.

**Step3: Evaluating key variables:** the next stage involves ranking of key variables making  
use of two criteria: degree of importance and degree of uncertainty. The idea is to identify  
two or three of the most important and uncertain variables from the ranking. Figure 2 presents  
the ranking of the key variables influencing the generation system of Ghana.

Figure 2 Evaluating driving forces in generation system of Ghana (Ghanadan & Koomey, 2005)

**Step 4: Developing scenarios logic:** The scenario logic is then developed based on the  
ranking exercise. The key is to end up with few policy scenarios with clear policy direction to  
assist decision makers. The scenarios are developed to revolve around the key variables and  
enriched by adding details making use of the other key factors. This is done by making use of  
each key structure or trend of the ranking.

The most uncertainty and important driving forces highlighted in Figure 2 form the  
basis for the development of the four scenarios analysed in this paper:

131 The Base Case scenario which assumes the current generation capacity addition in Ghana and  
132 shows increased expansion in thermal power generation which operates largely on natural gas  
133 (NG) and crude oil will continue into the future. The capacity addition of NRET were based  
134 on the national strategic plan (Energy Commission, 2006) and the most recent modification  
135 of the country's renewable penetration target presented as part of the country's Intended  
136 Nationally Determined Contribution (GH-INDC) presented to the United Nations Framework  
137 Convention on Climate Change (UNFCCC) during COP21 in Paris in December 2015, as  
138 well as the committed systems that are either currently under construction, or have been  
139 granted permits by Energy Commission of Ghana (Energy Commission, 2015). Existing  
140 thermal plants will continue to operate on both natural gas and crude oil with the aim to  
141 switch fully into natural gas by 2030 to conform to the existing national strategy. New  
142 thermal generation plants will be fuelled by natural gas.

143 Coal scenario is similar to the base case except with the introduction of coal plants to  
144 take share of new natural gas thermal plants. This scenario assumes the introduction of coal  
145 plants to meet 10% of new thermal plants that are to be constructed from 2016 onwards.

146 Modest RET scenario focuses on the promotion of renewable energy technologies  
147 which have significant potential. Thus PV, Wind, small Hydro, wave, biomass and MSW are  
148 integrated in moderate amounts with the aim of increasing the renewable capacity<sup>2</sup> to about  
149 20% by year 2030.

150 High RET Scenario explores the full potential of RET. Thus emphasis is placed at  
151 deploying renewable energy technologies based on confirmed domestic potential. This  
152 scenario assumes shifting of policy towards the development of low emission technologies  
153 with reduction in fossil fuel generation.

154 **Step 5: Analyses of the scenarios:** the final stage of the scenarios methodology used in this  
155 paper involves an analysis of the various scenarios in order to elaborate future generation  
156 development proposed by the various scenarios and their consequences. This involves the  
157 translation of the qualitative narration of the scenarios into quantity data and assessed using  
158 the Long-range Energy Alternative Planning (LEAP) energy planning tool. The Long-range  
159 Energy Alternatives Planning (LEAP) system developed by Stockholm Environmental  
160 Institute (SEI) is a widely used energy modelling tool for energy policy analysis and  
161 Greenhouse gases (GHG) emission mitigation studies, and is widely used especially in  
162 developing countries. Applications of LEAP for scenario analysis includes long term forecast

---

<sup>2</sup> Renewable energy in this case does not include Large hydro generation

163 of Taiwan's energy system (Huang, et al., 2011), analysis of alternative scenarios and their  
164 implications on the electricity sector of Lebanon (Dagher & Ruble, 2011), as well as that of  
165 Greece (Roinioti, et al., 2012) and for Cambodia and Laos (Luukkanen, et al., 2015). The  
166 model has also been applied for environmental and cost assessment of power scenarios in  
167 Nigeria (Gujba, et al., 2011). In Ghana LEAP was adopted for developing energy and  
168 emission scenarios as basis for the country INDC commitment (Republic of Ghana, 2015). A  
169 detail description of the LEAP methodology is available in Heaps (Heaps, 2012).

## 2.2 Development of Ghana LEAP demand Model

171 The Bottom-Up demand model approach in LEAP was adopted for modelling the  
172 future energy demand in this thesis. Bottom-Up or End Use approach provides a detailed  
173 engineering based modelling account for sectors as well as end users and energy consuming  
174 devices and is the most suitable method when assessing long term transitions (Heaps, 2012).  
175 The key factor in the development of future energy system is the projection of demand, which  
176 in turn depends on the demographic and macroeconomic indicators of the study area. A  
177 reliable energy system should be able to meet the demand requirement. The population of  
178 Ghana in 2010 was 24 658 845 million people which was projected to be increasing at a  
179 growth rate of 2.4% (Ghana Statistical Service, 2013). The electricity consumption pattern in  
180 Ghana varies significantly between urban and rural areas. In 2010, 83.8% of the urban  
181 households had access to electricity compared to only 39.5% of rural households. With the  
182 current average population growth rate of 55.8% in 2010, which is expected to increase to  
183 about 60% by 2040 (Ghana Statistical Service, 2013), the energy demand for domestic  
184 consumption is expected to increase significantly by 2040.

185 The Gross Domestic Product (GDP) average growth rate from 2005 to 2009 was about  
186 6% rising to a peak of 14% in 2011 as a result of the production of crude oil in commercial  
187 quantities in Ghana, which began in late 2010 (Ghana Statistical Service, 2016). The GDP  
188 growth rate of 8% was adopted for base case load projection from 2010 to 2020, increasing to  
189 12% from 2020 to 2040 when the power supply is expected to improve. The energy intensity  
190 data used for the model was developed from energy consumption survey conducted by the  
191 Energy Commission of Ghana in 2010 (Energy Commission, 2015).

192 The LEAP model was designed with 2010 as the base year, to analyse the possible  
193 developmental structure of the generation system of Ghana up to 2040. The choice the base  
194 year was due to availability of data: the national census conducted by the Ghana Statistical  
195 Service (Ghana Statistical Service, 2013) and a national energy survey by the Energy

196 Commission (Energy Commission, 2015) were conducted in 2010, providing reliable data for  
197 model. The selection of 2010 also provided opportunity to validate the results with real data  
198 for the past years (2010 to 2014).

199 The results of the energy demand projection from 2010 to 2040 using LEAP energy  
200 demand model is presented in Figure 3.

Figure 3 Electricity demand forecast

203 The results show that demand projection will increase into the future with an average demand  
204 growth rate of 9%, 8% and 8% within the periods of 2010 to 2020, 2020 to 2030 and 2030 to  
205 2040 respectively. These growth rates follow the historical demand growth of the country,  
206 and are consistent with official load projections (GRIDCO, 2011). Figure 3 further shows that  
207 the total energy requirement of Ghana by 2020 will be 18.88GWh increasing to 62.5 GWh at  
208 the end of the study period. This means that the current installed capacity of 2.19 GW will  
209 have to be expanded to 5.0 GW and 16 GW in 2020 and 2040 respectively, if the country is  
210 to be able to meet its future electricity requirement. This therefore requires the exploration of  
211 all energy sources available in the country and long term energy development and expansion  
212 plan if the country is to benefit from its expanding economy due to its recent oil and gas  
213 production.

214 It is important to note that the actual demand may be higher than the projection in this  
215 study. This is because the projections are based on historical demand and GDP values which  
216 themselves may not reflect the actual demand. The insufficient generation and low  
217 electrification rate especially in rural areas lead to suppressed demand. Thus the historical  
218 trends alone may not fully capture the real demand which is best captured by back casting  
219 (Bazilian, et al., 2012). This is confirmed by the trend in historical demand data of Ghana  
220 ( Energy Commission, 2015), which shows a negative demand growth during the energy  
221 crises in 2007. This clearly shows that the official demand projection is closely related to  
222 generating capacity. The focus of the paper is to explore possible pathways for sustainable  
223 power generation in Ghana and to undertake an environmental and economic analysis of the  
224 various scenarios. As a result, this demand will be used for all the scenarios.

225 The technology cost data was adopted from IEA (IEA, 2014), NREL (NREL, 2012)  
226 and GRIDCO (GRIDCO, 2011). The future year investment cost of the conventional energy  
227 systems in Ghana (large Hydropower and thermal power) were assumed to be constant  
228 throughout the study period while that of renewable systems were assumed to decrease

229 according to projections presented in IEA (2014). Table 1 shows the investment, fixed  
1 230 operational and maintenance (O&M) and variable O&M values considered in the LEAP  
2 331 model for the various times intervals considered in the study. Fixed operation and  
3 232 Maintenance (O&M) is the part of the maintenance cost of a plant which does not depend on  
4 233 the operation of the plant. Components of fixed O&M includes property tax and insurance,  
5 234 planned and unplanned maintenance, administration, operation staff as well as re-investments  
6 235 within the scheduled lifetime of the plant. Variable O&M generally refers to consumption of  
7 236 auxiliary material such as fuel additives, lubricants and lubricants, and treatment and disposal  
8 237 of waste. Renewable energy systems such as wind and PV have very low variable O&M  
9 238 which was considered to be zero in this paper

20 241

Table 1 Cost data considered in LEAP

21 242 The operation and maintenance cost were calculated using the percentage rates from National  
22 243 Renewable Energy Laboratory (NREL) cost and performance data for power generation  
23 244 technologies rates (NREL, 2012).  
24  
25  
26

27 245 The prices of fossil fuel resource are particularly very difficult to predict because of  
28 246 its high price fluctuations in the world market. However, the bench mark fuel price  
29 247 projections in IEA annual energy outlook 2015 (IEA, 2015) were considered as the most  
30 248 reliable assumptions and hence adopted for this paper. These prices are the average spot price  
31 249 in the United States and hence did not include local port as well as transportation charges.  
32 250 Even though Ghana started producing oil and gas in commercial quantities in 2010, the prices  
33 251 in the local market are determined by the international prices and are adjusted in line with  
34 252 fluctuations in the international market.  
35  
36  
37

38 253 To model the feedstock fuel of the thermal plants considered in the Ghana LEAP  
39 254 model, the actual crude oil and natural gas prices made available for power generation in  
40 255 Ghana were used for the reference years, that is, from 2010 to 2015. For the future years, the  
41 256 price projections in (IEA, 2015) were adopted. Transportation and taxes were calculated  
42 257 using 20% and 90% for crude oil and natural gas respectively to reflect the current price  
43 258 trend. Table 2 shows the fuel prices used in the LEAP model.

262 Ghana has no known coal reserves. The model therefor assumed that all coal will be  
1 263 imported. The coal price projections were therefore based on the projections, while  
2 264 transportation, taxes and processing charges were assumed to be 60%.

### 265 **2.3 Modelling the Generation System**

266 The dependent installed capacity of Ghana in 2010 was 1865 MW consisting of two  
3 267 large hydro dams with capacity of 1040 MW with the remaining contribution from six  
4 268 thermal power plants. To model the generation system of Ghana in LEAP, the various  
5 269 generating plants were aggregated. This means that single hydro and thermal plants were  
6 270 modelled to represent the system.

271 The operational characteristics of the plants used in modelling the generation system  
7 272 from 2010 to 2014 are presented in Table 3.

273  
274 Table 3 Operational characteristics of generation plans in Ghana

275  
276 The data in Table 3 was developed from actual plant operational data obtained from energy  
277 outlook of Ghana from 2011 to 2015 (Energy Commission, 2015). All the plants were  
278 modelled as combined cycle plants because plans are far advanced to convert all the  
279 remaining simple cycle plants into combine cycle (Energy Commission, 2006).

280 Most of the thermal plants in Ghana are designed to operate on LCO and natural gas.  
281 Natural gas is the preferred fuel when available because of its relative low cost and minimal  
282 environmental impact. However, because of insufficient supply, LCO continue to contribute  
283 almost half of the feed stock fuel (Energy Commission, 2015). The feedstock ratio of 55%  
284 NG and 45% LCO was assumed for 2010 to 2014. Beyond 2014, the ratio was interpolated to  
285 80% and 20% for natural gas and LCO by 2020 respectively, and eventually to 100% natural  
286 gas by 2030. This is in line with the proposals to operate the thermal plants fully on natural  
287 gas described in the Strategic National Energy Plan (SNEP) of Ghana (Energy Commission,  
288 2006).

## 289 **Results and Discussion**

### 290 **3.1 Technical**

291 The generation outlook of Ghana under various policy directions described in the scenarios is  
292 presented in Figure 4. It is observed from Figure 4 /that the installed capacity of Ghana will  
293 need to be expanded to at least 16 GW in order to meet demand and the specified reserved  
294 margin.

295

296

Figure 4 Installed capacities of scenarios

297

298 Higher installed capacities will be required for the RET scenarios. This is due to the relatively  
299 low capacity credit of renewables considered in higher capacities in RET scenarios and  
300 conforms to the finding of McPherson & Karney (2014) which suggest that higher capacities  
301 of RET need to be constructed to be able to meet the same demand as that of the thermal  
302 plants. The higher RET deployment will ensure higher diversity of the generation mix with a  
303 reduction of the thermal share of generation. This will result in 57% and 38% renewable  
304 share for high and modest RET scenarios respectively compared to only 18% for the base  
305 case.

### 306 3.2 Cost

307 The economic results of the scenarios expressed in 2010 US dollars, are presented in Table 4.  
308 O&M cost includes both fixed O&M and variable O&M. Environmental Externalities (Env.  
309 Ext.) costs were also captured to enable a quantification of the environmental effect of the  
310 scenario. The generation of power from fossil fuel leads to emission of Greenhouse gases  
311 (GHG) which has an adverse effect on society. The cost of these negative consequences  
312 therefore needs to be considered when appraising generation technologies. Currently, Ghana  
313 does not have a carbon tax mechanism in place; however, the study assumes an introduction  
314 of \$10 /tonne carbon tax in 2020 rising up to \$20 /tonne in 2030. The aim of this current  
315 study is not to achieve a level of carbon pricing that will overcome externalities associated  
316 with power production in Ghana but rather highlight the effect of the introduction of carbon  
317 tax on the various scenarios. Revenue from the sale of electricity was not capture in this  
318 analysis. This is because the same demand was applied to all the scenarios and the scenarios  
319 were modelled to meet this demand as well as the specified reserved margin. Thus the cost  
320 benefit summary in Table 4 expresses only the avoided transformation cost<sup>3</sup>, fuel purchase  
321 and environmental externalities cost compared to the base case scenario. These results may  
322 therefore not indicate the exact cost values for the scenarios; however, they provide useful  
323 benchmark for comparing their economic performance.

324

---

<sup>3</sup> Transformation cost = capital + O&M cost

325 Table 4 Cumulative discounted cost benefits 2010 to 2040 relative top base case scenario<sup>4</sup>

326  
327 It is observed from Table 4 that the capital and O&M costs of the alternate scenarios  
328 are higher than the base case scenario. At the reference discount rate (10%), an extra \$787  
329 million and \$2408 million in capital investment will be required to implement the modest  
330 RET scenario and the high RET scenarios respectively over the 30 year study plan  
331 considered. These results were not surprising considering the higher investment cost of  
332 technologies considered in the alternative scenarios. However, it was observed that the total  
333 Net Present Value (NPV) of the cost of the RET scenarios were lower than both the base case  
334 and coal scenarios. This is due to the significant savings in cost of fuel that occur in the two  
335 RET scenarios. These results show that the current generation system plan of Ghana (Base  
336 case scenario) is the obvious choice when consideration is given to only investment cost.  
337 However, the long term savings in fuel cost by the alternative scenarios over the study period  
338 of 2010 to 2040 increasingly makes the higher integration of RET into the generation plan a  
339 viable alternative. The trend in cumulated discounted cost/benefits of the scenarios over the  
340 study period is illustrated in Figure 5.

341  
342 Figure 5 Cumulated discounted cost benefits of scenarios (Discounted Rate =10%)

343  
344 The results in Figure 5 shows that economic benefits due to savings in fuel cost could be  
345 achieved within short term with modest introduction of renewables. However, high RET  
346 scenario will begin to yield economic benefits beyond 2033. This means that based on the  
347 assumptions and constrains used in developing the scenarios, RET can be deployed into the  
348 Ghana generation mix on their own merit when consideration is given to their long term  
349 benefits.

350 Table 4 further compares the NPV of the alternative scenarios under discount rates of  
351 5% and 15%. An immediate observation of the trend in NPV seems to suggest that the choice  
352 of discount rate does not significantly affect the choice of the alternative scenario compared  
353 to the base case as a similar trend was observed. However an analysis in terms of the  
354 cumulative NPV compared to the base case clearly shows that the lower the discount rate, the  
355 higher the present value of the future cash flows. It is observe from Table 4 that lower  
356 discount rate favour the RET scenarios which are dominated with high capital intensive

---

359 <sup>4</sup> Positive values represent extra cost while negative benefits, compared to base case scenario.

357 technologies. A key policy priority should therefore be geared towards the provision of  
358 guarantee long term finance to promote the high integration of RET.

359 The cost of fossil fuel was considered as the most important parameter that influences  
360 the cost of generation of the thermal plants, while that of RET is largely dependent on  
361 investment cost. These two parameters also have high variability in price: while the cost of  
362 RET especially wind and solar have seen a downward trend in capital cost; that of fossil fuel  
363 price is generally unstable. To this end, sensitivities on the capital cost of RET and cost of  
364 fossil fuel were undertaken to determine the effect of variation of these parameters on the  
365 economic performance of the scenarios.

366 Table 5 presents the NPV of the scenarios under the various fossil fuels and RET  
367 investment cost sensitivities. The top part of the table shows the cumulative NPV in 2010  
368 billion US dollars, while the bottom part compares the NPV of the alternative scenarios to the  
369 base case.

370 Table 5 Economic performance with fuel and RET investment cost sensitivities<sup>5</sup>

371  
372 It can be seen from Table 5 that the alternative scenarios are less expensive compared to the  
373 base case over the study period. This is mainly due to the higher fuel savings in the  
374 alternative scenario with increase in fuel cost. This trend is similar to the trend in Table 4 and  
375 seems to suggest that variation in fuel and RET investment cost does not significantly affect  
376 the comparative performance of the scenarios. However, a closer look at the percentage  
377 change of NPV compared to the base case shows a better understanding of the variation.  
378 Modest RET scenario's will be 3.69% to 4.77% less expensive, while that of high RET will  
379 be 9.59% to 13.23%, compared to the base case. It was however surprising to note that RET  
380 scenarios resulted in higher benefits with higher fuel prices. This was evidenced with the  
381 highest savings for the alternative scenarios occurring with HF + LR sensitivity. It can thus  
382 be suggested that the inclusion of modest to high RET into the generation mix of Ghana will  
383 not only help to diversify the generation system but will also lead to economic benefits of  
384 between 0.5% to 13.23% depending on the development of fuel and RET investment cost.  
385 This finding has important implications for developing of RET by showing that based on the  
386 current economic trends, technologies and energy resources in Ghana, higher penetration of  
387 RET is competitive on its own merit to conventional expansion when considered over a 30  
388 year period.

---

<sup>5</sup> key: LF = Low fuel cost; HF = high fuel cost; HR = high RET investment cost; LR = low RET investment cost

### 389 3.3 Environment

1 390 The Forth Assessment Report (AR4) 100 year GWP factors were adopted for this  
2  
3 391 study. This is in line with IPCC's 2013 conference of parties(COP 19) guidelines which  
4  
5 392 recommends that as of 2015, national communications should use the AR4 factors to ensure  
6  
7 393 uniformity in reporting (UNFCCC, 2014). The cumulative one hundred year direct GWP at  
8  
9 394 point of emissions of the scenarios compared to base case scenario is shown in Figure 6.  
10  
11 395 The environmental effect of the introduction of coal on the environment is evidenced by the  
12  
13 396 higher emission of the coal scenario compared to the cleaner NG generation in the base case.  
14  
15 397 The only difference between the coal and base case scenarios is the endogenous addition of  
16  
17 398 coal plants to take up a maximum of 20% of new natural gas plants share. The introduction of  
18  
19 399 coal plants has resulted in a cumulative emission of about 30 million metric tonne CO<sub>2</sub>eq  
20  
21 400 compared to base case (Figure 6).

22 401 Figure 6 Cumulative GHG emissions compared to base case scenario

23 402  
24  
25 403 There is currently no enforcement of CO<sub>2</sub> emissions limitation on power generation plants in  
26  
27 404 Ghana. This is because of the comparatively lower emission levels in the country because of  
28  
29 405 the relatively low emission factors. This has informed the continuous expansion of thermal  
30  
31 406 plants as represented in the base case scenario. Coal which has presently topped the list of  
32  
33 407 possible candidate plants, will lead to higher emission levels in the country. The contribution  
34  
35 408 of coal generation plants to global GHG emissions is further highlighted in the International  
36  
37 409 Energy Agency (IEA) world energy report (IEA, 2011). According to the IEA, even though  
38  
39 410 coal share of world generation in 2009 was 41%, it accounted for 73% of the world 11.8 Giga  
40  
41 411 tonne of CO<sub>2</sub> emissions for that year (IEA, 2011). Aside the major GHG, coal ash which is  
42  
43 412 solid waste produced after combustion, contains a number of toxins including arsenic,  
44  
45 413 cadmium, selenium. The adoption of the coal scenario will therefore be at the expense to the  
46  
47 414 environment. It is important for the country to consider the introduction of emission standards  
48  
49 415 with the liberalisation of the energy sector to encourage independent power producers to not  
50  
51 416 only invest in renewable energy but to continue to explore more efficient thermal generation  
52  
53 417 such as combine cycle gas plants

54 418 Figure 6 further confirms the general idea of the contribution of renewable energy  
55  
56 419 technologies in the reduction of CO<sub>2</sub> emissions. The results shows that if the country could  
57  
58 420 afford to follow the generation expansion plan proposed in the high RET scenario, about 90  
59  
60 421 million metric tonne CO<sub>2</sub>eq will be avoided over the study period, a reduction of about 40%

422 to the base case plan. It is however essential to further analyse the environmental effect of  
423 high introduction of biomass generation which was considered in higher capacities in the  
424 RET scenarios. This is because biomass generation lead to higher emission of photochemical  
425 oxidation (POCP) and Eutrophication (EP) (Gujba, et al., 2011) as well a source of  
426 particulate matter (PM1, PM2,5, PM10) and heavy metals (Paiano & Lagioia, 2016). Over  
427 exploitation of forest a reserve leading to deforestation is also possible with biomass  
428 generation. These negative implications were not considered in this study. There will  
429 therefore be the need to further assess this renewable energy source if the scenarios proposed  
430 in this study are to be adopted for implementation. However, Paiano & Lagioia (2016)  
431 suggested that innovation in bioenergy conversions could control these emmissions, while the  
432 cultivation of dedicated energy crops for power generation may help to solve the problem of  
433 deforestation (Zafeiriou, et al., 2016).

434 The environmental results in LEAP can also be expressed in terms of cost of avoided  
435 CO<sub>2</sub> emission. Cost of CO<sub>2</sub> avoided is the cost of reducing CO<sub>2</sub> emission to the atmosphere  
436 expressed as \$/tonne of CO<sub>2</sub> not emitted with respect to the base case scenario. The decision  
437 criterion is to identify the least cost alternative in reducing a tonne of CO<sub>2</sub>. The results of the  
438 cost of CO<sub>2</sub> avoided under different discount rates are shown in Table 6.

439  
440 Table 6 Cost of avoided CO<sub>2</sub> emissions (US \$/tonne of CO<sub>2</sub>eq)

441  
442 It is interesting to note that even though the GHG savings is higher in the high RET scenario,  
443 the modest RET scenario results in net higher benefits at 5% and 10% discount rates. It  
444 should be noted that cost of avoided CO<sub>2</sub> is not applicable to the coal scenario since it  
445 resulted in higher emission compared to the base case. These results show that Ghana could  
446 secure funding through Clean Development Mechanism (CDM) under the Kyoto protocol if  
447 the country makes maximum use of its abundant renewable energy potential. CDM allows  
448 developing countries to sell carbon credits to developing countries with mandatory  
449 greenhouse emission reduction targets.

#### 452 **4. Conclusions and Policy Implications**

453 This study explored a number of policy options that can be adopted to meet the  
454 increasing electricity requirements of Ghana based on the available energy resources and  
455 technologies. The generation system of the country will need to be expanded more than five

456 times from 2014 to 2040 if the country is to meet the future energy requirement. The country  
1 457 therefore faces a number of policy choices in balancing environmental implications and  
2  
3 458 social cost, as well as diversification of the system.  
4

5 459 The results show that an adaption of the coal scenario which is one of the official  
6  
7 460 generation options, will lead to cumulative incremental cost benefits compared to the base  
8  
9 461 case scenario as a result of fuel cost savings over the study period. However, this will be at  
10  
11 462 the expense of environmental implications, as the coal scenario will lead to overall higher  
12  
13 463 100 year global warming potential. RET scenarios offer favourable options if the appropriate  
14  
15 464 choice is based on environmental and net incremental cost. The significant increase in capital  
16  
17 465 cost is the main hindrance for implementing the RET scenarios. However, the results show  
18  
19 466 that significant savings in fuel cost over the study period will be sufficient to offset the capital  
20  
21 467 investment resulting in net benefits. A long term perspective is thus critical and suggest that  
22  
23 468 RET deployment can be cost effective on their own merit compared to conventional fossil  
24  
25 469 fuel generation when considered over long term horizon.

26 470 Diversification of the generation mix with renewable energy technologies will reduce  
27  
28 471 the overall fossil fuel generation which is characterised by unreliable feedstock fuel supply as  
29  
30 472 well as price shocks. The results show significant greenhouse emissions savings is achieved  
31  
32 473 in the RET scenarios resulting in net benefits in cost of avoided emissions compared to the  
33  
34 474 base case. These findings suggest that if the country could afford to develop its generation  
35  
36 475 system with high deployment of RET, additional benefits in the form of carbon trading under  
37  
38 476 the Kyoto could be achieved. This will have significant implication for further development  
39  
40 477 of renewables with availability of funds which is the main obstacle for the implementation of  
41  
42 478 these technologies.

43 479 The results reveal that overall benefits are achieved with higher integration of RET.  
44  
45 480 Even though high integration of RET require higher capital investment, significant savings in  
46  
47 481 fuel cost over the study period lead to overall benefits with higher integration of RET.  
48  
49 482 Sensitivities on the development of fuel prices and investment cost of RET revealed that, the  
50  
51 483 integration of modest to high RET into the generation mix will lead to economic benefits of  
52  
53 484 0.5% to 13.23% depending on the costs development over the 30 year study period. The high  
54  
55 485 RET offers the highest economic and environmental benefits. Policy direction should  
56  
57 486 therefore explore mechanisms which will lead towards higher development of RET  
58  
59 487 technologies.  
60  
61  
62  
63  
64  
65

488 The main weakness of this study is the key assumptions used in the model. It was not  
1 possible to explicitly determine the development of fossil fuel prices into the future  
2 489  
3 considering historical price fluctuations. Also investment cost of energy technologies are site  
4 490  
5 specific, thus using average values may not fully represent the cost at a particular location.  
6 491  
7 The cost results in this study should therefore be interpreted with caution and should  
8 492  
9 therefore not be considered as the exact cost values for the scenarios. Nonetheless the results  
10 493  
11 provided a useful benchmark for analysing the possible generation pathways.  
12 494

13 495 Further studies need to be carried out to assess the impact of high penetration of  
14 496  
15 renewable generation technologies on the stability of the grid as well has grid expansion  
16 497  
17 studies to accommodate the potential generation expansion.
