Keywords: Vanadium dioxide; Adaptive stealth; Low emissivity; Al-based composites

### ABSTRACT

Vanadium dioxide (VO<sub>2</sub>) is assumed as a promising dynamic infrared stealth material owing to its tuneable emissivity. However, the relatively high emissivity associated with VO<sub>2</sub>-based adaptive infrared stealth materials poses a constraint on their practical applications. To address this issue, this proposed a VO<sub>2</sub>/Al composite endowed with a smart infrared stealth function. With 50% VO<sub>2</sub>, the composite achieved a low emissivity value of 0.54 at 30 °C, while it exhibited a reversible variation to 0.43 at 100 °C, demonstrating a change up to 0.11. When the temperature of the sample remained at 100 °C, the surface temperature detected by an infrared camera was only 53.4 °C, indicating a promising infrared stealth performance. Meanwhile, the metal-insulator transition (MIT) effect and thermal insulation performance were investigated under the framework of the composition effect of composite materials. The design strategy of this metal composite material paves the way for novel approaches in designing dynamic infrared stealth materials with low emissivity.

### 1. Introduction

The infrared stealth materials minimize the difference in infrared radiation between the target and its background through the radiation adjustment, thereby effectively evading detection and achieving stealth capabilities [1, 2]. Achieving an effective infrared camouflage effect necessitates that stealth materials exhibit superior environmental adaptability. This is crucial because the intensity of solar radiation, temperature, humidity, and other dynamic factors can significantly impact the infrared radiation intensity during

actual operations. However, conventional stealth materials possess a fixed emissivity and can only conceal objects against a specific background temperature. Consequently, when the environmental condition changes, the conventional stealth materials become susceptible to re-exposure. Therefore, it is imperative to develop an intelligent material that can adapt its emissivity spontaneously to match the surrounding environment [3–5]. Vanadium dioxide ( $\text{VO}_2$ ) has attracted much attention due to its reversible metal-insulator transition (MIT). It undergoes a phase transition from a monoclinic structure (M phase) with insulating properties to a tetragonal rutile structure (R phase) with metallic properties at the critical temperature  $T_c \approx 68^\circ\text{C}$  [6, 7]. Accompanied by the phase transition, the infrared emissivity of  $\text{VO}_2$  changes significantly, from high emissivity at low temperature to low emissivity at high temperature [8, 9]. The variable emissivity of  $\text{VO}_2$  can be used to maintain the minimum difference between the object and the background in terms of radiation energy under a variable temperature environment, thus offering a practical approach for adaptive infrared camouflage. Moreover, the MIT temperature of  $\text{VO}_2$  can be effectively tuned through doping [10–12], strain [13, 14] and intrinsic point defects [15, 16]. Ji et al. demonstrated the tunability of infrared radiation intensity of  $\text{VO}_2$  nano-powders in two thermal atmospheric windows for the first time [17]. Following this, W-doped  $\text{VO}_2$  nanoparticles were successfully prepared to reduce the transition temperature and the results further promote the development of the adaptive camouflage [18]. Nevertheless, the emissivity of  $\text{VO}_2$  in the M phase is as high as 0.8–0.9, which will result in a high intensity of infrared radiation and thus not be favourable for its application in camouflage according to the infrared stealth mechanism [19].

Given the ultra-low emissivity exhibited by metals such as gold, silver, and aluminium [20, 21], the combination of low-emissivity materials with dynamic stealth materials can be an effective strategy for enhancing infrared stealth performance. Based on lightweight design and cost considerations, in this work, Al powders were ball milled with  $\text{VO}_2$  particles and spark plasma sintered (SPS) to form bulk composites in order to reduce the emissivity. The impact of  $\text{VO}_2$  content on emissivity was experimentally evaluated, and the emissivity characteristics of the composites were analysed using an infrared thermal imaging camera. Furthermore, the thermal and electrical conductivity properties of the composites, along with their three-dimensional microstructure, were systematically investigated to explore the MIT effect and thermal insulation performance. These findings may offer valuable guidance for the development of smart infrared stealth materials with reduced emissivity.

## 2. Experimental

$\text{VO}_2$  particles (99.99 wt % purity, the average size of  $3\ \mu\text{m}$ ) and pure Al particles (99.95 wt % purity, the average size of  $25\ \mu\text{m}$ ) were milled using a planetary high energy ball mill under an argon atmosphere to prepare Al-(10, 20, 30, 40, 50) vol%  $\text{VO}_2$  composite powders. The ball-milling process was conducted at ambient temperature for 4 h (with a 20 min

interval for every 60 min milling time ) at a rotation speed of 200 rpm, and the ball-to-powder weight ratio was 10:1 . The obtained powder was sintered at 500 °C for 10 min under an axial pressure of 50 MPa using SPS.

The microstructure of the polished samples was observed using a scanning electron microscope (SEM , Phenom XL , Phenom -World) . Energy -dispersive spectroscopy (EDS ) was employed to analyse elemental mapping with an operation voltage of 15 kV . A Talos F200 X G2 transmission electron microscope (TEM ) with selected area electron diffraction (SAED) was used to confirm the crystal structure . X -ray diffraction (XRD ) patterns were acquired on a Rigaku Ultima IV diffractometer (Rigaku, Japan) using Cu K  $\alpha$  radiation (  $\lambda = 0.154 \text{ nm}$  ) with a scan speed of  $2^\circ / \text{min}$ . The electrical conductivity (  $\sigma$  ) measurement was conducted by the standard four -probe technique in a Quantum Design Physical Property Measurement System (PPMS) . The heating and cooling rates were set at  $5^\circ \text{C} / \text{min}$ . Thermal conductivities of the composites ,  $\kappa$  , were obtained through a calculation that is equal to the product of density (  $\rho$  ), heat capacity (  $C_p$  ), and thermal diffusivity (  $D$  ),  $\kappa = \rho \cdot C_p \cdot D$  . Here ,  $\rho$  was measured using the Archimedes drainage method.  $C_p$  was determined by differential scanning calorimetry (DSC 2500 , TA).  $D$  was obtained by the laser flash diffusivity method (LFA467, Netzsch , Germany). The infrared emissivity of the composites was investigated on the IR - 2 dual band emissivity measuring instrument (Shanghai Institute of Technical Physics, China) at the wave - length of  $8 - 14 \mu \text{m}$  under different temperatures. X -ray microtomography was performed on Zeiss Xradia 620 with a pixel size of  $0.7 \mu \text{m}$  . The thermal images at different temperatures were taken by an infrared thermal imager working in the  $8 - 14 \mu \text{m}$  region (Magnify Technologies).

### 3. Results

The microstructure of VO<sub>2</sub>/Al composites with varying VO<sub>2</sub> volumetric fractions is depicted in Fig. 1(a–e), while Fig. 1(f) displays the EDS mapping for a composite containing 20 vol% VO<sub>2</sub>. Combining with EDS results, the grey phase was pure Al, which uniformly surrounded VO<sub>2</sub> particles in the whole picture. With the increasing volume fraction Fig. 1. (a–e) SEM images of VO<sub>2</sub>/Al composites with various VO<sub>2</sub> contents, (a) 10 vol%, (b) 20 vol%, (c) 30 vol%, (d) 40 vol%, (e) 50 vol%, and (f) EDS mapping of the composite with 20 vol% VO<sub>2</sub>. (g) TEM image of 20 vol% VO<sub>2</sub>/Al composite and the corresponding SAED pattern of (h) Al and (i) of VO<sub>2</sub>, the bright VO<sub>2</sub> particles aggregated within the Al matrix and formed a VO<sub>2</sub> network. Fig. 1(g) shows the TEM image of 20 vol% VO<sub>2</sub>/Al composite, indicating the good interfacial bonding of VO<sub>2</sub> and Al. The SAED patterns in Fig. 1(h) and (i) revealed the well crystallization of Al and VO<sub>2</sub>. Fig. 2 exhibits XRD patterns of VO<sub>2</sub>/Al composites at room temperature. The peaks of the XRD patterns were identified according to Al (JCPDS Card No. 99-0005) and VO<sub>2</sub> (M) (JCPDS Card No. 43-1051). It suggested that the obtained composites consisted of Al and VO<sub>2</sub> (M) without any impurities.

To investigate the MIT effect of the composites, the temperature dependence of electric Al conductivity ( $\sigma$ ) is shown in Fig. 3. The conductivity of pure VO<sub>2</sub> is also plotted. It can be seen that  $\sigma$  decreased from  $7.24 \times 10^5$  S/m to 0.97 S/m with the content of VO<sub>2</sub> increased from 10 vol% to 50 vol% within the lower temperature range, gradually approaching the electric Al conductivity of pure VO<sub>2</sub>. At higher temperatures, the value of  $\sigma$  showed the same trend. The more the VO<sub>2</sub> contained, the higher the increase was. The conductivity jumps were clearly presented on all samples around 68 °C. Considering the consistency of the conductivity of Al, the conductivity variation of the composite can be attributed to VO<sub>2</sub> due to the presence of the MIT within a similar temperature range.

In order to further identify the MIT properties of each sample, the variation of the electric Al conductivity change ( $\Delta A$ ) and  $\tau_c$  of the MIT Fig. 2. XRD patterns of the VO<sub>2</sub>/Al composites with various VO<sub>2</sub> contents. Fig. 3. Effect of temperature on the electric Al conductivity of VO<sub>2</sub>/Al composites with different contents of VO<sub>2</sub>. The solid and dashed lines present data during the heating and cooling processes, respectively. were also

calculated. The results were plotted with respect to the VO<sub>2</sub> contents, as shown in Fig. 4.  $\Delta A$  was defined as the ratio of conductivity at 120 °C and 40 °C, corresponding to the metallic phase and semiconductor phase of VO<sub>2</sub>, respectively. It can be seen in Fig. 4 that  $\Delta A$  first increased from 3.7 at 10 vol% VO<sub>2</sub> to 77.4 at 30 vol% VO<sub>2</sub>, and then decreased to 56.2 at 40 vol% VO<sub>2</sub>. This is because  $\Delta A$  is primarily affected by two different mechanisms. First,  $\Delta A$  was closely related to the VO<sub>2</sub> content, a higher VO<sub>2</sub> concentration led to a larger  $\Delta A$ . Second, when the content of VO<sub>2</sub> is too high, defects such as pores may enhance the scattering effect on electrons, leading to smaller jumps of electric Al conductivity. Therefore, there was a slight decrease in  $\Delta A$  when VO<sub>2</sub> content was 40 vol%. For 50 vol% VO<sub>2</sub>/Al composite,  $\Delta A$  was up to 3.14 orders of magnitude again, which was comparable to those reported for pure VO<sub>2</sub> [22,23]. The large change of the electrical conductivity indicated that 50 vol% VO<sub>2</sub>/Al composite has excellent MIT behaviour. The accurate  $\tau_c$  can be defined from the first-order deviation of the conductivity variation in the heating and cooling stages. As shown in Fig. 4,  $\tau_c$  was increased from 60.56 °C for 10 vol% VO<sub>2</sub> to 71.73 °C for 50 vol%. The findings suggested that the transition temperature of the composites can be affected by manipulating the volume fraction of VO<sub>2</sub>, which have been reported in previous studies [24–26].

The temperature dependences of the emissivity are shown in Fig. 5. The emissivity of pure VO<sub>2</sub> is also characterized and shown in Fig. 5. With the lower VO<sub>2</sub> contents (10–40 vol%), the composites showed a constant emissivity at different temperatures. In general, the emissivity of the composite is determined by the intrinsic emissivity of VO<sub>2</sub> and Al. Since the emissivity of VO<sub>2</sub> at room temperature is much higher than that of pure Al, the emissivity of the composite increased from 0.13 of 10 vol% to 0.28 of 40 vol% with the increase of VO<sub>2</sub> content. The consistency of the emissivity with temperature was broken off when the addition of VO<sub>2</sub> was increased to 50 vol%. It revealed distinctive emissivity changes in the heating and cooling cycles indicating an inherited MIT from VO<sub>2</sub>. A thermal hysteresis loop was also observed. It was found that the infrared emissivity could reversibly change from 0.54 at 40 °C (below  $\tau_c$ ) to 0.43 at 120 °C (above  $\tau_c$ ), showing a pronounced infrared emission regulation up to 0.11. This regulation may be due to the increase in electric Al conductivity change. It was proved that the infrared emissivity of a material is inversely proportional to its electric Al conductivity [27]. The MIT temperature for emissivity change can be defined at 68.4 °C for the composite with 50 vol% VO<sub>2</sub>, which is quite consistent with previous reports [9,28]. Therefore, when the VO<sub>2</sub> content reaches as high as 50 vol%, the composite exhibits a distinct switching characteristic, and its emissivity is lower than that of pure VO<sub>2</sub>. It provides new prospects for the application of adaptive infrared stealth material with low emissivity.

In addition to the emissivity, the infrared stealth performance of the material is also closely related to the thermal conductivity [29]. According to Stefan Boltzmann's Law, the infrared radiation intensity emanating from an object is directly proportional to its surface temperature and infrared emissivity. Therefore, low thermal conductivity can effectively

decelerate heat transfer to the surface, thereby reducing the intensity of infrared radiation. The thermal conductivity of the composite with different VO<sub>2</sub> contents is shown in Fig. 6. Thermal conductivity of pure Al [30] and pure VO<sub>2</sub> [31] are also shown for comparison. Due to the relatively lower thermal conductivity of VO<sub>2</sub>, the thermal conductivity of the composites decreased with the increase in VO<sub>2</sub> content. Even with a small amount of VO<sub>2</sub> addition, the value of the thermal conductivity dropped unexpectedly rapidly from 49.4 Wm<sup>-1</sup>K<sup>-1</sup> of 10 vol% to 12.6 Wm<sup>-1</sup>K<sup>-1</sup> of 20 vol%. When the volume fraction of VO<sub>2</sub> exceeded 20%, the VO<sub>2</sub> network formed. The thermal conductivity was then dominated by VO<sub>2</sub>. It in turn showed a lower thermal conductivity of around 5 Wm<sup>-1</sup>K<sup>-1</sup>, nearly identical Al to that of pure single-crystal VO<sub>2</sub>. Meanwhile, the thermal conductivity of the composite did not show any obvious change across the investigated temperature range. The low thermal conductivity of the samples ensures that heat cannot be rapidly transferred to the surface, thereby facilitating the application of adaptive infrared stealth materials.

In order to further evaluate the infrared radiation properties of the VO<sub>2</sub>/Al composites, thermal images were taken in the 8–14 μm band using an infrared camera. The imaging system is illustrated in Fig. 7(a). The bulk 50 vol% VO<sub>2</sub>/Al composite and pure VO<sub>2</sub> that were used for the measurement were both 1 mm in thickness and had similar surface morphology. Samples were equilibrated for at least 5 min at each temperature before data collection. The thermal infrared images of 50 vol% VO<sub>2</sub>/Al composite and pure VO<sub>2</sub> are presented in Fig. 7(b), illustrating the correlation between the radiation temperature captured by the infrared camera and the real temperature. As shown in Fig. 7(b), when the real temperature reached 30 °C, which was below  $\tau_c$ , the radiation temperatures of 50 vol% VO<sub>2</sub>/Al composite and VO<sub>2</sub> were 17.7 °C and 27.3 °C, respectively, with a radiation temperature difference of 9.6 °C. When the real temperature was raised to 100 °C, which was higher than  $\tau_c$ , the radiation temperature difference was 14.1 °C. Variation of the infrared radiation temperature of bulk 50 vol% VO<sub>2</sub>/Al and pure VO<sub>2</sub> at different real temperatures is shown in Fig. 7(c). The radiation temperature of the 50 vol% VO<sub>2</sub>/Al and pure VO<sub>2</sub> increased linearly with the increase in the real temperature before  $\tau_c$ . However, the radiation temperature of both samples changed significantly after the phase transition. The results show that the 50 vol% VO<sub>2</sub>/Al composite effectively reduces the thermal emissivity of pure VO<sub>2</sub> and has excellent adaptive infrared stealth performance.

## 4 . Discussion

### 4. 1 . Agaric model for electrical conductivity

The abrupt change in the emissivity of the composite promises a potential infrared stealth material for smart devices. It is well known that the electrical and thermal conductivity of a material are important factors affecting its thermal stealth performance. Therefore , it is of great significance to explore the VO<sub>2</sub> content effect on the electrical conductivity and thermal insulation performance of the VO<sub>2</sub>/ Al composite. The Agari mode I was first proposed in 1986 to explain the li near relationship between the logarithm of thermal conductivity and the volume contents of particles in composites [32]. Note that al l the data points of electrical conductivity change with VO<sub>2</sub> content are approximately on a straight line , the experimental data can be used to fit the Agari equation in the form of electrical conductivity, as follows :

$$\log \sigma = V \cdot C2 \cdot \log \sigma_2 + (1-V) \cdot \log(C1 \cdot \sigma_1) \quad (1)$$

where  $\sigma$  stands for the electrical conductivity of the composite,  $\sigma_1$  is the electrical conductivity of material 1 ( Al in the present study) , and  $\sigma_2$  is the electrical conductivity of material 2 ( V O 2 in the present study) .  $V$  is the volume content of material 2.  $C_1$  is a coefficient of the effect on crystallinity and crystal size of material 1, and  $C_2$  is a coefficient of ease in forming conductive chains of material 2 [33].

As shown in Fig. 8(a ) and (b), the equation fits well with the experimental results. (The data required in the mode I are obtained according to the literature [34 ,35]. ) Value s of coefficients  $C_1$  and  $C_2$  in Eq . (1 ) are 2.10 8 and  $- 11.78 7$  at 40 °C , 1.43 2 and 2.32 1 at

120 °C . A larger value of C1 indicates a greater effect of VO2 particles on the electrical conductivity of Al . It seems reasonable to speculate that the VO2 particles may influence Al and alter the electrical conductivity of composites at lower temperatures because of the large difference in electrical conductivity between M -phase VO2 and Al . While at the higher temperature of 120 °C , the value of C2 becomes higher . It suggests that VO2 particles are more prone to forming conductive chains at 120 °C (above  $\tau_c$ ) than at 40 °C (below  $\tau_c$ ) . This phenomenon may be attributed to the metallic state of VO2 at 120 °C , characterized by higher conductivity.

#### 4. 2 . GEM mode I for thermal conductivity and the VO2 network configuration

The general effective media (GEM ) equation combines the percolation theory and the effective medium theory to construct a quantitative model, which is widely used in the electrical conductivity, thermal conductivity, particle diffusion , etc. of two -phase composites [36 –38]:

$$\frac{v_1(\kappa_1^{1/t} - \kappa^{1/t})}{\kappa_1^{1/t} + [f_c/(1 - f_c)]\kappa^{1/t}} + \frac{v_2(\kappa_2^{1/t} - \kappa^{1/t})}{\kappa_2^{1/t} + [f_c/(1 - f_c)]\kappa^{1/t}} = 0 \quad (2)$$

where  $v_1$  stands for the volume fraction of the low -conductivity component, and  $v_2$  stands for the volume fraction of the high - conductivity component. Similarly,  $\kappa_1$  and  $\kappa_2$  denote the thermal conductivities of the low - and high -conductivity components, respectively .  $\kappa$  represents the thermal conductivity of the composites .  $f_c$  is a parameter related to the critical volume fraction for the low -conductivity phase, and  $t$  is an exponent.

The relationship between thermal conductivity and VO2 content at room temperature is fitted using the GEM equation . The result is shown in Fig. 9. (The data required in the model are obtained according to the literature [31 ,34 ,39]. ) The model predictions are in good agreement with the measured values. The derived mode I parameters for the composite include a critical volume fraction ( $f_c$ ) of VO2 of 0. 2 and a critical exponent ( $t$ ) of 0.167. The computed percolation threshold indicates a sharp decrease in thermal conductivity when the volume fraction of VO2 is about 20 %, which suggests that VO2 particles form effective conductive networks in the composites . Therefore , the conduction through Al is impeded. Beyond the percolation threshold, the thermal conductivity stabilizes, approaching that of VO2 , suggesting that VO2 dominates thermal transport in this region.

In our experiment, at lower VO2 content , the discrete distribution of VO2 particles within the pure Al matrix suggests that the continuity of pure Al offers a bypass route for the movement of the electrons and phonons. With a high content of VO2 particles, a continuous VO2 network forms, which interferes with the movements of electrons and phonons. To further prove this hypothesis, a 3D configuration of VO2 particles in the

composite was investigated using micro-CT analysis on the Zeiss Xradia 620 Versa device. As shown in Fig. 10, when the volume fraction of VO<sub>2</sub> is 10%, most of the VO<sub>2</sub> particles are isolated from each other and the connectivity is only 27.29%. Therefore, the transport of electrons and phonons must go through the interaction of both Fig. 8. Agaric model I fitted with experimental results of the electrical conductivity for VO<sub>2</sub>/Al composites as a function of the VO<sub>2</sub> volume fraction at (a) 40 °C and (b) 120 °C, respectively. The conductivities are thus dominated by Al networks. However, when the VO<sub>2</sub> content is 20 vol% or higher, the conductivities are tuned by VO<sub>2</sub> connections because the VO<sub>2</sub> connectivity increases rapidly at 20 vol% to 70.32% and then reaches equilibrium when the VO<sub>2</sub> content is 30 vol%. The results further elucidate that the thermal conductivity of the composite depends on the formation of VO<sub>2</sub> conductive chains, confirmed by the GEM model, and its percolation threshold is 20%.

## 5 . Conclusions

In the present study, VO<sub>2</sub>/Al composites with adaptive infrared stealth properties were successfully prepared by ball milling and SPS. The VO<sub>2</sub> content had an important effect on the stealth performance of the composite. When the amount of VO<sub>2</sub> was 50 vol%, the emissivity of the composite varied with increasing temperature, from 0.54 to 0.43 with an emittance variability of 0.11. The results of the infrared thermal images showed that compared with pure VO<sub>2</sub>, the radiation temperature of the 50 vol% VO<sub>2</sub>/Al composite decreased by 9.6 °C and 14.1 °C before and after the phase transition. Moreover, the low thermal conductivity of the composites indicated that they have good thermal insulation performance. In addition, the variation of electrical and thermal conductivities of the composites with VO<sub>2</sub> content was investigated to reveal the transport mechanism. It is shown that the thermal and electrical transport were consistent with the GEM model and the Agaric model respectively. This VO<sub>2</sub>/Al composite exhibits broad application prospects in the fields of adaptive infrared camouflage with low emissivity.
